Abstract. The first goal of this manuscript is to argue that phrasal Temporal Adverbial Constructions (TACs) like Al left before Pat are derived via ellipsis from an underlying clausal source. The second goal is to demonstrate and account for the restricted distribution and interpretation of these reduced phrasal TACs relative to their clausal counterparts and TACs targeted by VP-Ellipsis. The proposed analysis provides evidence for a Parallelism condition on ellipsis and supports models for an identity condition on ellipsis that allow the identification of an antecedent within the phrase structure representation of the utterance.

1. Introduction

Temporal Adverbial Constructions (TACs) introduced by the connectives before and after come in both full clausal (1a) and phrasal forms (1b).

(1) a. Al left [ before Pat left ]
   b. Al left [ before Pat ]

A question, which is familiar from the literature on comparative constructions (see Kennedy 1999 and Lechner 2004), concerns the status of the phrasal TAC in (1b). One possibility is that before and after can combine directly with either clausal complements or nominal complements. A less obvious possibility is that phrasal TACs are derived from a clausal counterpart through a reduction mechanism such as ellipsis. In this scenario, the phrasal TAC in (1b) is more accurately represented as in (2).

(2) Al left [ before Pat left ]

The goal of the first half of this paper is to argue that at least some phrasal TACs in English are derived from a clausal source. This argument is partially in response to arguments presented in Penka & von Stechow 2011 against this approach to phrasal TACs. I show that several of the arguments in Penka & von Stechow 2011 do not hold up to closer scrutiny and instead provide

---

Thank you to Dustin Chacón, Tom Ernst, Tom Grano, Claire Halpert, Jesse Harris, Kyle Johnson, Brian Reese, Hooi Ling Soh, Ricard Viñas de Puig, and four anonymous reviewers for Syntax for helpful comments and discussion. Portions of this work have also benefited from exposure to audiences at the 2018 Meeting of the Linguistics Society of America, the University of Minnesota, and Wayne State University, and Indiana University. The responsibility for any errors or misrepresentations of the ideas of others lies solely with the author.
Reduced Temporal Adverbs support for a reduction analysis. We will see that additional diagnostics also converge on the idea that phrasal TACs in English can have an underlying clausal source.

That phrasal TACs are reduced from a clausal source has been gestured at by Geis (1970) and pursued by both Larson (1987) and Thompson (2005). However, I argue that these exact implementations suffer from technical shortcomings and fail to adequately account for the full range of facts regarding phrasal TACs. The facts to be presented lead us to an alternative reduction analysis for phrasal TACs that I refer to as TAC-Stripping, shown in (3).

(3) \[
\begin{array}{c}
\text{vP} \left[ \text{vP} \text{ Al left} \right] \\
\text{beforeP} \text{ before} \\
\text{FocP} \text{ Pat}_{1} \langle \text{vP} \text{ left} \rangle
\end{array}
\]

Phrasal TACs on this account are low-adjoined on the verbal spine and contain a truncated complement to the temporal connective, roughly an extended vP. Their internal syntax is likened to Stripping constructions as proposed by Depiante (2000). A single remnant can be generated by \(\text{A}\)-movement to a focus position outside the elided vP. This analysis is similar in spirit to Pancheva’s (2009) analysis of Slavic comparatives and Weir’s (2014b) analysis of Why-Stripping.

The second half of this paper demonstrates and accounts for a puzzle presented by the restricted distribution of reduced TACs relative to their full clausal counterparts, as well as TACs that contain a VP-Ellipsis site. The empirical generalization that underlies this puzzle is stated in (4).

(4) No Asymmetric Embedding

A TAC-Stripping site and its antecedent must be at the same level of embedding.

This generalization captures the fact that, while TACs can generally be adjoined to various positions on the verbal spine, phrasal TACs with a reduced clausal source cannot be adjoined to a predicate that does not resolve its interpretation. As will also be discussed, behavior similar to that described by (4) has been observed in Gapping and other Bare Argument Ellipses (Hankamer 1979, Rooth 1992b, Lechner 2004, Johnson 2019). However, I argue that available accounts for these effects in other domains do not lend themselves to a treatment of TACs.

I present an account of the generalization in (4) that treats the restricted distribution of reduced clausal TACs as a symptom of the inability to satisfy a focus-based identity condition on ellipsis (Rooth 1992a). In this way, ellipsis is found to be eliminative with respect to phrase structure representations. Certain phrase structure representations are blocked as a result of irreparable antecedent-containment. In other representations, the syntax-semantics of TACs as temporal relative clauses, as motivated by Geis (1970) and Larson (1990), means that the TAC-Stripping site will fail to find an appropriate antecedent that contains a parallel operator-variable dependency. This approach will be motivated by the implausibility of stating the identity condition on TAC-
Reduced Temporal Adverbs

Stripping over a salient question meaning in the discourse (e.g., AnderBois 2011, Barros 2014, Weir 2014a).

This analysis is very much inspired by the one that Takahashi (2008) provides for under-applications of VP-Ellipsis in other environments identified by Hardt & Romero (2004). However, I will argue that an account of the differing distributions of VP-Ellipsis and TAC-Stripping requires giving up the precise implementation in Takahashi 2008. I will argue that VP-Ellipsis targets a constituent that is smaller than what is possible for TAC-Stripping. The effect is that VP-Ellipsis is able to identify antecedents that are not available to TAC-Stripping. Thus, the differences between VP-Ellipsis and TAC-Stripping are also reduced to the ability to satisfy an identity condition on ellipsis.

In section 2 I present the argument that at least some phrasal TACs are derived from a clausal source by way of ellipsis. In section 3 I present and motivate the basic syntax of the TAC-Stripping operation that generates these reduced clausal TACs. In section 4 I present the restricted distribution of reduced TACs relative to their clausal counterparts. In section 5 I present a slightly more articulated syntax for TACs and an account of the available data. In section 6 I demonstrate and account for the fact that TACs that have been targeted by VP-Ellipsis have a slightly wider distribution than those targeted by TAC-Stripping. I conclude the article in section 7.

2. The Clausal Status of Phrasal TACs

Relative to clausal and phrasal comparative constructions, like those in (5), discussion about the relationship between clausal and phrasal TACs in (6) is sparse.

(5)  
\begin{align*}
\text{a. Ann left later [ than Phil left ]} & \quad \text{(6) a. Ann left [ after Phil left ]} \\
\text{b. Ann left later [ than Phil ]} & \quad \text{b. Ann left [ after Phil ]}
\end{align*}

Nevertheless, the expected approaches are represented. One analysis asserts that the string in (6b) belies the syntax. In this kind of “direct phrasal” analysis, the temporal connective combines directly with a nominal complement. A straightforward implementation of this idea would assign phrasal TACs structures like in (7).

(7) \quad \text{Ann [VP left [afterP after [DP Phil ]]]}

The challenge for direct analyses is to assign this representation the appropriate interpretation wherein Phil is also construed to have left.

Penka & von Stechow (2011:sec.5) present a slightly more articulated syntax for phrasal TACs to do exactly this. Abstracting away from the precise details of the lexical semantics of the temporal connective, which are modeled on Heim’s (1985) treatment of comparatives, they suggest that the
sentence in (7) is paired with an LF representation like in (8b), where entities are of type \( e \), times are of type \( i \), and propositions are of type \( t \).

\[(8)\]  
\[\text{a. } \langle \text{it} \rangle \]
\[\text{DP } \text{Ann } \langle \langle e, \text{it} \rangle \lambda 3 \langle \text{it} \rangle \lambda 1 \text{VP : } t \]
\[x_3 \text{ left}(t_1) \]

\[\text{b. } t \]
\[\text{DP } \text{Ann } \langle \langle e, \text{it} \rangle \rangle \lambda 3 \langle \text{it} \rangle \lambda 1 \text{VP : } t \]
\[t_2 \text{ after } \text{DP } \text{Phil} \]

This representation is generated, first, by an application of Quantifier Raising (QR) that moves the DP \text{Ann} out of the VP; see (8a). The phrasal adjunct is then counter-cyclically adjoined to the verbal spine in a position below the landing site of QR. The result, shown in (8b), is the adjunction of a TAC containing a temporal variable and the nominal element \text{Phil}. It is the semantics of the temporal connective that ensures the root clause predicate is applied to the TAC-internal DP.

An alternative analysis, which suggests that the phrasal TAC is reduced from a clausal source, is pursued by both Larson (1987) and Thompson (2005). We will consider the details of these “reduced clausal” analyses in section 3.2. For the time being, it is enough to note that these authors have representations like (9) in mind.

\[(9)\]  
\[\text{Ann left } [\text{afterP after } [\text{Phil left}]]\]

The nominal element \text{Phil} in the representation above is the remnant of an ellipsis operation that renders the rest of the embedded clause unspoken.

The substantive difference between these two families of analyses is the amount of linguistic material proposed to be inside the TAC. Direct analyses predict that a phrasal TAC will not show evidence of additional linguistic material beyond the nominal constituent—and possibly a temporal variable—inside the TAC. Reduced analyses predict that there will be evidence of clausal linguistic material inside the TAC that shares some identity with the material of the root clause.

Penka & von Stechow (2011) present a number of diagnostics for both English and German as evidence for the direct analysis of phrasal TACs. In the remainder of this section I will review
the arguments that speak to the syntax of phrasal TACs in English.\textsuperscript{1} Where we are able to make conclusions, I will argue that the data are consistent with or actually support the availability of a reduced analysis of phrasal TACs in English. I will also present some additional data sets that also point toward a clausal source for English phrasal TACs. Before examining these arguments, it will be worthwhile to consider a prosodic property of phrasal TACs.

### 2.1 Focus Sensitivity

Like other Bare Argument Ellipses, there is a general preference for placing the nominal constituent in a phrasal TAC in contrastive focus with a correlate in the root clause.\textsuperscript{2} The pair of examples in (10) demonstrate the point with a pronominal remnant.

\begin{equation}
\text{(10)} \quad \begin{array}{ll}
\text{a.} & \text{Kim met Sue before THEM.} \\
\text{b.} & \text{*Kim met Sue before 'em.}
\end{array}
\end{equation}

The strong pronominal \textit{them} in (10a) serves as an acceptable remnant while the weak, unstressed \textit{'em} in (10b) is highly degraded, if not ungrammatical.

Moreover, it was observed as early as Geis (1970) that phrasal TACs that modify a transitive predicate, like in (11) and (12) below, are ambiguous. Rooth (1992b) notes further that the placement of focus in the root clause serves to disambiguate these configurations.

\begin{equation}
\text{(11)} \quad \text{KIM met Sue before TOM.} \quad \text{(12)} \quad \text{Kim met Sue before TOM.}
\end{equation}

\begin{quote}
\text{‘Kim met Sue before Tom met Sue.’} \quad \text{‘Kim met Sue before Kim met Tom.’}
\end{quote}

When the root clause subject carries a pitch accent in (11), \textit{Tom} is interpreted as the subject of another meeting event. A pitch accent on the root clause object in (12) indicates that \textit{Tom} should be interpreted as the object of another meeting event.

This does not rule out a direct analysis, but it is arguably expected under an analysis where \textit{Tom} is the remnant of a clausal ellipsis operation. Assuming Rooth’s (1992b) theory of focus

\begin{equation}
\text{(i)} \quad \begin{array}{ll}
\text{a.} & \text{Kate spoke to Nate \{earlier than / before\} Frank.} \\
\text{b.} & \text{Kate spoke to Nate \{?earlier than / *before\} to Frank.}
\end{array}
\end{equation}

At present, I am unable to provide a satisfactory account of this contrast, which is a priori unexpected under a reduced clausal analysis. I hope that future research will be able to shed light on this puzzle. Regarding restrictions on the number of remnants, I will defer discussion of the relevant observation until section 3.2.3 and footnote 13, when we will have a more explicit picture of the proposed syntax of reduced clausal TACs.

\textsuperscript{1}In addition to the arguments to be examined, Penka & von Stechow (2011) argue for a direct phrasal analysis on the basis of the restricted category and number of elements inside a phrasal TAC. Concerning the first of these, phrasal TACs, unlike other reduced clausal constructions, do not tolerate non-DP categories to the same extent. A relevant pair of examples is provided in (i).

\textsuperscript{2}I will use \textsc{small caps} to indicate the pitch accent associated with contrastive focus.
interpretation, focus placement in the root clause presupposes that the focus semantic value of the root clause includes the ordinary semantic value of the embedded clause ($[\text{Emb}]^o \in [\text{Root}]^f$).

(13) a. $[\text{Root} \text{ Kim met Sue}]$ before $[\text{Emb TOM1} \langle \text{met Sue} \rangle]$
    $[\text{Emb}]^o = \text{Tom met Sue} \in$
    $[\text{Root}]^f = \{ p : x \text{ met Sue} \mid x \in D_e \}$

b. $[\text{Root} \text{ Kim met SUE}]$ before $[\text{Emb} \langle \text{Kim met} \rangle \text{TOM1}]$
    $[\text{Emb}]^o = \text{Kim met Tom} \in$
    $[\text{Root}]^f = \{ p : \text{Kim met } x \mid x \in D_e \}$

When the root clause subject has a pitch accent there will be a presupposition that the embedded clause is a member of the set of focus alternatives derived from the root clause. As shown in (13), this requires interpreting Tom as the subject of the embedded clause. A similar explanation can be provided for when Tom is interpreted as the object.

2.2 Binding Connectivity

Recall that direct and reduced analyses of phrasal TACs make different predictions with respect to the presence of unspoken linguistic material in the TAC. Building on Lechner (2004), we can probe for the existence of linguistic material in phrasal TACs by investigating the binding relationships of the remnant. If there is additional, unspoken linguistic material in the phrasal TAC, the remnant should be sensitive to the binding properties of that material.

Penka & von Stechow (2011) present the contrast in (14) as evidence that phrasal TACs involve directly combining the temporal connective with a DP. They point out that (14a) is acceptable on a subject interpretation of the remnant.

(14) a. ?Mary saw Peter$_1$’s sister [ before him$_1$ ].
   b. *Mary saw Peter$_1$’s sister [ before he$_1$ saw Peter$_1$’s sister ].

(Penka & von Stechow 2011:443, (35)–(36))

The claim is that the lack of a disjoint reference effect in (14a) indicates that the phrasal TAC does not have a clausal source. If it did, the Condition C effect found in (14b) would be expected.

There is confound in this experiment that undermines the intended conclusion, however. A known property of ellipsis configurations, shown in (15), is that they fail to display expected Condition C effects.

(15) Mary saw Peter$_1$’s sister [ before he$_1$ did see Peter$_1$’s sister ].
This is one effect of what Fiengo & May (1994) refer to as Vehicle Change.\(^3\) Regardless of the exact source of Vehicle Change effects, the lack of a Condition C violation in (14a) could equally signal the need for a direct analysis or for a reduced clausal analysis of this phrasal TAC.\(^4\)

If we are indeed observing Vehicle Change effects in (14a), then we correctly expect to observe a disjoint reference effect in minimally differing examples like (16a) below. A subject interpretation of the remnant induces a Condition B violation, as illustrated by the clausal version in (16b).

\[(16)\]
\[\begin{align*}
\text{a. } & *\text{MARY praised } \text{Peter}_1 \text{ [ before HIM}_1]. \\
\text{b. } & *\text{MARY praised } \text{Peter}_1 \text{ [ before HE}_1 \text{ praised him}_1].
\end{align*}\]

These facts together support a reduction analysis of this phrasal TAC, which displays a characteristic property of ellipsis. A potential concern about the data in (16a) could be that it is actually the DP Peter in the root clause that is triggering the Condition B violation. This would undermine the conclusion that the phrasal TAC contains unspoken linguistic material. The example in (17) is provided to demonstrate that this is not the case.

\[(17)\] Mary\(_2\) praised Peter\(_1\) [ before HE\(_1\) praised HER\(_2\)].

When the Condition B configuration in the TAC is resolved, the resulting string is grammatical. Thus, the root clause object cannot be held responsible for the disjoint reference effects in (16).

On a similar note, Penka & von Stechow (2011) also provide the paradigm in (18) in support of a direct analysis for phrasal TACs.

\[(18)\]
\[\begin{align*}
\text{a. } & *\text{Mary saw him}_1 \text{ [ before Peter}_1 \text{'s sister].} \\
\text{b. } & \text{Mary saw him}_1 \text{ [ before Peter}_1 \text{'s sister saw him}_1]. \\
\text{c. } & \text{Mary saw him}_1 \text{ [ before Peter}_1 \text{'s sister did].}
\end{align*}\]

(Penka & von Stechow 2011:443–444, (40)–(41))

They point out that the ungrammaticality of (18a) is not expected under a reduction analysis of phrasal TACs. If the phrasal TAC had a reduced clausal structure, then it would pattern with the grammatical examples (18b) and (18c). Instead, the argument goes, the ungrammaticality suggests that the phrasal TAC does not embed a clause, which ultimately leads to a Condition C violation.

The example in (18a) is also not obviously consistent with a direct phrasal analysis of this

\(^3\)An anonymous reviewer points out that they do not find the example in (14a) grammatical on the intended interpretation but that they do find (15) to be grammatical. One way to interpret this is that TAC-Stripping does not bleed Condition C effects for all speakers.

TAC. For (18a) to induce a Condition C violation, the direct object of the root clause *him* would c-command *Peter’s sister*. However, this would presumably also be true in (18b) and (18c), leading incorrectly to the expectation that these examples would also incur Condition C violations. Note that a similar point can be made about the examples below in (19) and (20a), where a direct object again fails to trigger a disjoint-reference effect associated with Condition C.

That being said, the judgement in (18a) is one that neither I nor several other English speaking linguists who I have consulted share. To the extent that (18a) is relatively degraded, this is intuitively due to the ambiguity regarding the grammatical role of *Peter’s sister*, which is necessarily resolved in (18b) and (18c). This effect tends to be alleviated by placing a pitch accent on *Mary*.

Given the variability in the judgments regarding the paradigm in (18), we can also consider the following ditransitive structure, which has been adapted from Bhatt & Takahashi (2011).

(19) Jane took him₁ to Sue [ before Joe₁’s boss took him₁ to Sue ].

The first thing to note about this example is that the pronominal direct object of the root clause predicate does not trigger a disjoint reference effect with *Joe* in the TAC. Knowing this, it is revealing to find that the subject/object ambiguity for a remnant, familiar from section 2.1, is missing from the examples in (20). Specifically, the remnant *Joe’s boss* can receive a subject interpretation, but a disjoint-reference effect disrupts an indirect object interpretation.

(20) a. **JANE** took him₁ to Sue [ before Joe₁’s **BOSS** *(took him₁ to Sue)]
   b. *Jane took him₁ to Sue [ before *(Jane took him₁ to) Joe₁’s **BOSS**]

The observation that a disjoint reference effect is a function of the interpreted grammatical role of the remnant is exactly what is expected from the assertion that there is additional linguistic material inside the phrasal TAC. An instance of *Joe’s boss* is c-commanded by an elided instance of the coreferential pronoun only when interpreted as the indirect object in (20b).

Importantly, we see in (21) that an indirect object interpretation for the remnant is otherwise available.

(21) a. **JANE** took Joe₁ to Sue [ before his₁ **BOSS** *(took him₁ to Sue)]
   b. Jane took Joe₁ to **SUE** [ before *(Jane took him₁ to) his₁ **BOSS**]

An anonymous reviewer points out that they do not find (18a) to be ungrammatical, but it is still marginal relative to the rest of the paradigm. However, they point out that, regardless of a pitch accent on *Mary*, this example is unambiguous for them, permitting only a subject interpretation. Another reviewer reminds that the facts regarding the ability for the direct object to bind into adjuncts are not straightforward and become more complicated when one also considers bound-variable interpretations; see Valmala (2009) and Barker (2012). This all suggests that more systematic investigation of this paradigm will be necessary.
By swapping the positions of the spoken pronoun and R-expression, the relevant ambiguity emerges. Again, this is expected under a reduction analysis. The elided material in the matrix clause no longer induces a Condition C violation under either the subject or indirect object interpretation of the remnant *his boss*.

2.3 *Quantifier Phrases*

Penka & von Stechow (2011:444–445) also investigate the behavior of quantificational DPs in phrasal TACs. They argue that a quantificational DP would be expected to interact freely with quantificational elements in the root clause if a phrasal TAC had a direct syntax. This would not be possible given a reduced clausal source seeing as “quantifier scope is generally clause bounded.” A relevant test sentence, adapted from Penka & von Stechow (2011:445, (44)), is provided in (22).

(22) A secretary cried after each executive.
   a. $\exists > \forall$: ‘There is some secretary $x$ such that, for each executive $y$, $x$ cried after $y$ cried.’
   b. $\forall > \exists$: ‘For each executive $y$, there is some secretary $x$ such that $x$ cried after $y$ cried.’

As indicated, this example permits both a surface-scope and inverse-scope interpretation of the quantificational DPs *a secretary* and *each executive*.

This experiment also suffers from a confound, which is acknowledged by Penka & von Stechow (2011) and calls into question any conclusions regarding the status of a phrasal TAC. The example in (23) illustrates the observation—credited to Artstein (2005)—that quantificational DPs embedded in clausal TACs also seem to interact with quantifiers in the matrix clause.

(23) A secretary cried after each executive resigned.
   a. $\exists > \forall$: ‘There is some secretary $x$ such that, for each executive $y$, $x$ cried after $y$ resigned.’
   b. $\forall > \exists$: ‘For each executive $y$, there is some secretary $x$ such that $x$ cried after $y$ resigned.’ (Penka & von Stechow 2011:445, (44))

Given the lack of contrast between the data points above, the behavior of quantifiers inside phrasal and clausal TACs does not obviously help us choose between these analyses.

A more telling diagnostic can be found in the behavior of quantificational DPs in the root clause. Consider the difference in the available interpretations for the string in (24).

a. specific: ‘Dale read a certain book after May read the same book’

On the specific interpretation, it is possible to interpret the TAC to mean that May read the same book that Dale read. On the non-specific interpretation, May read a different book than the book that Dale read. This contrast can be understood, first, by asserting that the phrasal TAC in (24) in fact has an underlying clausal source that has been reduced by ellipsis. This makes it possible to model the ambiguity by proposing different material in the ellipsis site in the way shown below:

a. specific : \[\text{afterP after [May (read it)]}\]

b. non-specific : \[\text{afterP after [May (read a book)]}\]

The specific interpretation arises as part of the Vehicle Change family of effects discussed by Fiengo & May (1994). More concretely, we can propose that the ellipsis site contains an E-type pronoun that can be counted as equivalent, with respect to the identity condition on ellipsis, to the existentially quantified a book in the root clause (Elliot et al. 2014; cf. Barker 2012). The non-specific interpretation arises when there is an independent instance of a book present in the ellipsis site. This is not a result that is obviously expected from the direct phrasal analysis of the TACs sketched above. Under that analysis, there is a single instance of a predicate read a book that is applied both to the matrix subject and the TAC-internal DP. Thus, only the specific interpretation is expected.

A reduction analysis of (24) also leads us to expect that the relevant ambiguity will not be observed with other connectives that do not involve clausal ellipsis. It is not immediately clear that this prediction is borne out. The following sentence contains a comitative with-PP, which has no plausible clausal counterpart, but is compatible with either a scenario in which Dale and Mary read a single book or a scenario in which they each read a different book.6

(26) Dale read a book with May (*read \{it/a book\}).

There is evidence suggesting that this is a false-positive. Whatever the source of the vagueness in (26) is, it is arguably not a result of ellipsis.

The evidence can be drawn from the missing antecedent effects introduced by Grinder & Postal

---

6 An anonymous reviewer points out that they do not get the non-specific interpretation of (26). To the extent that this is a general intuition about this sentence, it supports the argument that non-ellipsis constructions lack the syntactic content to produce the non-specific interpretation in (25).
Reduced Temporal Adverbs

(1971) and employed by Hankamer & Sag (1976). The observation is that existential quantifiers under negation fail to introduce an antecedent for pronouns. This is demonstrated by the inability for *it* to refer to *a camel* in (27). The fact that *it* finds an antecedent given the ellipsis construction in (28), is taken by Hankamer & Sag (1976) to support the presence of linguistic material in an ellipsis site. The reasoning is that *it* is provided an antecedent by an instance of *a camel* in the ellipsis site.

(27) *Ivan has never ridden a camel and it stank horribly.

\( \text{it} = \text{a camel that Ivan has ridden} \) (adapted from Hankamer & Sag 1976:404, (25))

(28) I’ve never ridden a camel but Ivan has \( \langle \text{ridden a camel} \rangle \) and it stank horribly.

\( \text{it} = \text{a camel that Ivan has ridden} \) (adapted from Hankamer & Sag 1976:403, (23b))

In light of these data, consider the minimal pair of examples below. The intended antecedent for *it* is missing from the surface structure in (29), which contains a phrasal TAC. Nevertheless, the specific interpretation is possible. In contrast, *it* fails to find the intended antecedent in the comitative *with*-PP in (30).

(29) Dale didn’t write an abstract \[ \langle \text{after May wrote an abstract} \rangle \] because it was so good.

\( \text{it} = \text{the abstract that May wrote} \)

(30) *Dale didn’t write an abstract \[ \langle \text{with May} \rangle \] because it was so good.

\( \text{it} = \text{the abstract that May wrote} \)

A straightforward way to understand this contrast, which is also illustrated in these examples, is through the claim that the phrasal TAC contains elided linguistic material that provides the missing antecedent. Because the *with*-PP in (30) is not derived from a clausal source, the antecedent for *it* is missing. The result is the observed ungrammaticality.

2.4 Island Effects

In addition to the claim that phrasal TACs can be generated by way of ellipsis, the analysis sketched in section 1 asserted that the remnant undergoes an instance of A-movement out of the elided constituent. To the extent that the DP contained in a phrasal TAC is sensitive to island conditions, both of these positions would find support (e.g., Merchant 2004).

Among the relevant island conditions are the Complex-NP Constraint and the Left-Branch Condition, both catalogued by Ross (1967). The examples in (31) and (32) show respectively that phrasal TACs are sensitive to both the Complex-NP Constraint and the Left-Branch Condition.
(31) a. They hired someone who knows a BALKAN language  
    before they hired [DP someone [CP who knows a SLAVIC language]]  
  b. They hired someone who knows a BALKAN language  
    before [DP someone [CP who knows a SLAVIC language]](they hired x)
•  c. *They hired someone who knows a BALKAN language  
    before a SLAVIC language(they hired [DP someone [CP who knows x]])

  b. Abby read FRAN’s book after [DP GREG’s book](she read x)  
  c. *Abby read FRAN’s book after GREG( she read [DP x’s book])

The (a) variants of the examples above provide the full clausal version of the TAC. The (b) variants present a phrasal TAC with nominal elements that contain the island environment. Note that in both cases the contrastively focused element can grammatically appear inside the island environment. The (c) variants demonstrate that the contrastively focused element cannot on its own act as the nominal of a phrasal TAC on the intended interpretation.

These paradigms suggest that the nominal element in a phrasal TAC is somehow sensitive to island environments. This is expected under a reduction analysis along with the additional assumption that the remnant is A-extracted from the ellipsis site.

2.5 Section Summary and Discussion
The data presented in this section collectively support the claim that phrasal TACs can be derived via ellipsis from a clausal source. The results from the previous subsection suggest, moreover, that the remnant is extracted from the elided constituent. Note that the claim here is only that phrasal TACs can be reduced from a clausal source by ellipsis, not that they all must be. There are examples, such as the ones below, that are amenable to a direct phrasal analysis, like the one in Penka & von Stechow 2011. To the extent that such examples have a clausal counterpart, the content of the TAC and the root clause do not fit any definition of identity that would be expected to permit ellipsis.

(33) Paul left before dinner (began).         (34) Kim left after the movie (ended).

The picture that is emerging from this study, therefore, is that English has both direct phrasal as well as clausal TACs, the latter of which may surface in a form reduced through the instance of ellipsis to be investigated below.

This is a conclusion also reached by Larson (1987:261) as well as Thompson (2005:76–77), and may not necessarily be seen as surprising (cf. Geis 1970 and Penka & von Stechow 2011).
First, this makes phrasal TACs a counterpart to likePs according to Yoshida (2013) and to comparative constructions according to Lechner (2004)—more on this in section 3.2.3. Additionally, other languages seem to overtly betray this property of TACs. Larson (1987:260, fn.20) notes that full and reduced clausal TACs in Spanish are distinguished from their direct phrasal counterparts by the presence of the complementizer que ‘that.’ The same is true of Catalan. Direct phrasal TACs like in (35), which do not have a plausible clausal source, embed complements that are necessarily introduced by de ‘of,’ and cannot contain que ‘that.’ Full clausal complements of temporal connectives, on the other hand, are necessarily introduced by que ‘that,’ as shown in (36).  

(35) En Ricard va marxar [després de (*que) la conferència]  
    the Ricard AUX leave.PAST.3S after of that the lecture  
    ‘Ricard left after the lecture.’  

(36) En Ricard va marxar [després (%de) *(que) l’ Elena marx’es]  
    the Ricard AUX leave.PAST.3S after of that the Elena leave.PAST.3S  
    ‘Ricard left after Elena left.’  

In a way similar to the construction we have investigated in this section, a reduced version of (36) is possible and can be found in (37).  

(37) En Ricard va marxar [després (%de) *(que) l’ Elena ⟨marx’es⟩]  
    the Ricard AUX leave.PAST.3S after of that the Elena leave.PAST.3S  
    ‘Ricard left after Elena.’  

Of particular interest is that the complementizer que ‘that’ is again obligatory. This is a fact that can be understood if (37) is treated, not as a direct phrasal TAC, but a phrasal TAC that has been reduced from a clausal source.

The claim made in this section is also not that all languages have a reduction mechanism for clausal TACs. As an anonymous reviewer points out, there is compelling evidence suggesting that, while German has both phrasal and clausal TACs, the latter do not have reduced forms. Like Catalan, German also distinguishes lexically between phrasal and clausal TACs, but does so by way of the choice of temporal connective (Penka & von Stechow 2011:440–441). Direct phrasal TACs, like (38), are introduced by the temporal connectives vor ‘before’ and nach ‘after,’ which assign dative case. Clausal TACs, like in (39), are introduced by the temporal connectives bevor ‘before’ and nachdem ‘after.’

7Non-standard dialects of Catalan permit de que ‘of that’ in both full clausal and reduced clausal TACs (pers. comm. Ricard Viñas de Puig).
(38) Peter drank Whiskey [vor/nach dem Abendessen] the whiskey before/after dinner.  
‘Peter drank the whiskey before/after dinner.’  
(adapted from Penka & von Stechow 2011:440, (24c))

(39) Peter drank Whiskey [bevor/nachdem er das Bier getrunken hatte] the whiskey before/after he had drunk the beer.  
‘Peter drank the whiskey before/after he had drunk the beer.’  
(adapted from Penka & von Stechow 2011:440, (24a))

The anonymous reviewer also presents the contrast in (40). Like other embedded finite clauses, finite clausal TACs appear post-verbally in non-V2 environments; see (40a). As (40b) shows, there is no reduced version of this TAC that is comparable to English and Catalan.

(40) a. weil sie das Haus verließ, [bevor ich es verlassen hatte] because she the house left before I it had  
‘because she left home before I left it’

b. *weil sie das Haus verließ, [bevor mir/ich] because she the house left before me/I  
‘because she left home before me’

Interestingly, there is a phrasal treatment available for (40), which is provided by the reviewer in the form of (41). In this example, the TAC appears with the temporal connective vor ‘before’ and a dative DP. Moreover, the TAC patterns with PPs in that it appears in a pre-verbal position.

(41) weil sie das Haus [vor mir.DAT] verließ because she the house before me left  
‘because she left home before me’

Collectively, these data suggest that German does not have reduced clausal TACs. Instead, candidates for this treatment pattern with PPs with respect to word order and with other direct phrasal TACs with respect to the temporal connective and case properties of the TAC-internal DP.

These observations reveal a rich vein of future research. For those languages that show evidence for a clause reduction strategy for TACs, like Catalan and English, we should ask what properties they share. For languages that do not have a clause reduction strategy for TACs, like German, we should ask what contributes to the difference between these two sets of languages. In the remainder of this manuscript, however, I focus on providing an account of reduced clausal TACs in English and, as we will see, their restricted distribution relative to other TACs.
3. TAC-Stripping

Assuming that we have correctly diagnosed at least some phrasal TACs as having a clausal source that is reduced by ellipsis, we turn to providing a syntactic analysis for them. I will first present and motivate the basic internal and external syntax of phrasal TACs targeted by ellipsis. For convenience I will refer to this particular application of ellipsis as TAC-Stripping. I will then present several previous and alternative analyses along with the challenges they face.

3.1 Low-adjointed Small Clauses

The basis for the analysis to be proposed here comes from the treatment of canonical Stripping provided by Depiante (2000). The basic picture, which I am referring to as TAC-Stripping, is sketched in the partial representation provided in (42).

(42)  a. Kim met Sue after Tom.

\[
\begin{array}{c}
\text{vP} \\
\text{vP} \\
\text{Kim met Sue} \\
\text{after} \\
\text{FocP} \\
\text{Tom_1} \\
\langle \text{vP} \rangle \\
\text{Kim met} \\
\end{array}
\]

TAC-Stripping involves $\overline{A}$-movement of the remnant to a Focus phrase (FocP) outside of the elided constituent.\(^8\)

\(^8\)TAC-Stripping, as presented, employs movement to the left edge of the reduced clausal TAC. This is at odds with Hooper & Thompson’s (1973) claims about what is possible in clausal TACs. Future research will hopefully reconcile these facts by appealing to the truncation account being provided. While unreduced clausal complements to temporal connectives lack a sufficiently articulated left periphery, as argued for by Sawada & Larson (2004) and Haegeman (2006), the hypothesis is that small clause complements contain the relevant structure to allow this movement.

An anonymous reviewer inquires about the exact nature and motivation for such a position. One possibility is that this is the position employed in instances of Heavy-NP Shift (HNPS) like (i).

(i) Kim bought $x_1$ for her friends — some coffee$_1$.

A portion of the literature on HNPS has converged on the idea that it targets a low position at the edge of the predicate and results in focus effects for the displaced constituent (see Overfelt 2015).

What is relevant for the purposes of the analysis is that constituents with focus properties can appear at the periphery of the vP. A word is in order, however, regarding the difference in the type of focus being explored. The peripheral constituent in HNPS is usually thought to show presentational focus properties, by way providing the answer to a question (Rochemont & Culicover 1990). The analysis presented in the manuscript hypothesizes that the remnant of
The evidence to be presented suggests that the constituent being deleted is an extended projection of the predicate, which I will identify as vP. This vP is part of a truncated complement of a necessarily low-adjoined temporal connective.

3.1.1 Small Clause Analysis

The reduced size of the elided constituent makes this analysis very similar to the treatment of Slavic comparatives by Pancheva (2009) and to the treatment of Why-Stripping in English by Weir (2014b). The following examples are intended to demonstrate that the temporal connectives before and after are capable of embedding verbal small clauses that can be quite small.

(43) You should cook the dumplings [ before eating them ].

(44) The dumplings were eaten [ after being cooked ].

In these sentences, an embedded main verb in (43) and the passive voice morpheme in (44) appear in their gerundive form in the absence of the progressive auxiliary be. This suggests an absence from these examples of the tense, modal, or aspectual structure that is normally taken to appear above the vP in finite clauses. The reasoning is that the gerundive morphology in these examples is the default morphology that results from the absence of t⁰, which (45) shows do not seem to otherwise license gerundive morphology, at least outside of nominalizations (see Abney 1987).

(45) *Sue leaving.

The impossibility for modals in these constructions, as shown below, also indicates that t⁰ and its associated categories are missing from the clausal gerunds that can be embedded in TACs.⁹

(46) a. *Sue left [ before Kim might leaving ]
    b. *Sue left [ before Kim mighting leave ]

Next, a portion of the research on Gapping has suggested that those constructions at least can TAC-Stripping is interpreted with “contrastive” focus. Moreover, I will provide evidence in section 4.3 that the content of a TAC cannot provide the answer to a question, suggesting it is not presentationally focused. This discrepancy in how focus is interpreted could be made to follow from the idea that the interpretation of focus is a function of the anaphoricity of focus marking. Roughly in the terms of Rooth 1992b, it could be that, when focus marking cannot be anaphoric to a question, focus cannot be interpreted as presentational and, in the cases at hand, will be contrastive. Fully exploring and developing this idea is outside the scope of this manuscript, however, and must be left for future research.

⁹This is not to say that aspect cannot be projected in the clausal gerunds embedded by before and after. This is clearly possible: Sue left after having eaten. The point to be had at this point is that these temporal connectives are capable of embedding very small clausal complements.
Reduced Temporal Adverbs

involve low coordination in the phrase maker, making the conjuncts relatively small constituents. Taking Lin (2002) and Johnson (2009) as representative cases, it has been argued that it is VPs or vPs that are coordinated. These analyses have been motivated in part by observations from Oehrle (1987) and Siegel (1987) that sentential negation and modals resist being interpreted in the gapped constituent.

We can observe similar behavior with phrasal TACs. Looking at the scope of modals first, consider the example in (47).

(47) Stan can leave after Phil.
   a. $\equiv$ ‘Stan can leave at a time $t$ that is after a time $t'$ that Phil leaves at.’
   b. $\not\equiv$ ‘Stan can leave at a time $t$ that is after a time $t'$ that Phil can leave at.’

This example has an interpretation whereby Stan is able to leave after whatever time it is that Phil actually leaves at. That is, this sentence is true in a context where Phil is not allowed stay on his own, so Stan is required to stay until after Phil leaves. Missing from this sentence is the interpretation expected to arise if it were possible to interpret the ellipsis site with an instance of can. That is, (48) is not a possible way of understanding (47).

(48) Stan can leave after Phil can leave.

The interpretation missing from (48) then, is one where the time that Stan is permitted to leave at is later than the time that Phil is permitted to leave at. This interpretation is expected to be missing given the assertion that the deleted constituent in a phrasal TAC is not large enough to host modal auxiliaries, like in (46).

Similar effects arise with sentential negation. The TAC-Stripping site in (49) resists an interpretation that would signal the presence of negation in the ellipsis site.

(49) Pam didn’t leave after Beth.
   a. $\equiv$ ‘Pam left, but it’s not the case that she did so after Beth left.’
   b. $\not\equiv$ ‘Pam left, but it’s not the case that she did so after Beth didn’t leave.’

This sentence is true in a context where Pam left but this did not happen after the time at which Beth left. Among other interpretations that are missing for the string in (49) is one that describes a situation in which Pam left and it is asserted that this did not happen after an event in which Beth stayed, Pam in fact left before Beth didn’t leave. In other words, it is not possible to interpret negation inside the phrasal TAC. Note that the absence of this interpretation from a phrasal TAC
does not reflect an absence of this interpretation generally. The unreduced clausal TAC below is intended to provide this interpretation, though this is admittedly an odd way of expressing it.

(50) Pam didn’t leave after Beth didn’t leave.

The inability to interpret negation in the ellipsis site of a phrasal TAC is consistent with the claim that the elided constituent is no larger than a vP plus a focus projection to catch the remnant.

### 3.1.2 Low-adjunction

The interaction of sentential negation and phrasal TACs also provides evidence that TAC-Stripping only targets TACs that are adjoined relatively low to the verbal spine. In order to appreciate this, let us first observe that clausal TACs can be interpreted at various positions on the verbal spine within a single clause. This is evidenced by the scopal ambiguity of *after*-phrases with respect to sentential negation, as shown in (51).

(51) Pam didn’t leave after Beth left.
    a. \( \text{after} \mathrel{>^\neg} \lambda P \lambda Q . \forall t (P(t) \rightarrow \exists t' (Q(t') \land t' < t)) \) : ‘After Beth left, it’s not the case that Pam left.’
    b. \( \neg > \text{after} \) : ‘Pam left, but it’s not the case that she did so after Beth left.’

The high-scope interpretation of the TAC in (51a) could be uttered in a context where, after Beth’s departure, Pam decided not to leave and instead stayed. When the TAC is interpreted within the scope of negation in (51b), the sentence could be uttered in a context where Pam left, but this in fact occurred before Beth left.\(^{10}\)

\(^{10}\)It is a curious property of beforePs that they do not display the same type of ambiguity with respect to sentential negation that we find with afterPs. This is shown in (i).

(i) Pam didn’t leave before Beth left.
    a. \( *\text{before} > \neg \) : ‘Before Beth left, it’s not the case that Pam left.’
    b. \( \neg > \text{before} \) : ‘Pam left, but it’s not the case that she did so before Beth left.’

The precise nature of this asymmetry is likely to be orthogonal to the discussion at hand. Although, this makes afterPs crucial to the experiments with negation that are being run in the subsection.

It is possibly interesting to note, however, that the QR-based treatment of TACs adopted in section 5.1 plus some na"ive lexical entries for the temporal connectives (Anscombe 1964; cf. Beaver & Condoravdi 2003) may also help us understand this fact.

(ii) a. \( [\text{before}] = \lambda P \lambda Q . \exists t (P(t) \rightarrow \exists t' (Q(t') \land t' < t)) \)
    b. \( [\text{after}] = \lambda P \lambda Q . \exists t (P(t) \land \exists t' (Q(t') \land t' > t)) \)

The resistance to scoping over sentential negation that beforePs show could be understood as an instantiation of the dis-preference that universally quantified expressions have for scoping over sentential negation (e.g., Beghelli & Stowell...
It is interesting, in light of this general ambiguity, to find that a phrasal variant of the example above, provided in (52), only has the low-scope interpretation for the TAC.

(52)   Pam didn’t leave after Beth.
   a. *afterP > ¬: ‘After Beth left, it’s not the case that Pam left.’
   b. ¬ > afterP: ‘Pam left, but it’s not the case that she did so after Beth left.’

This sentence is only true in a context where Pam left, but she did so before Beth left (52b). It lacks the interpretation, available in (51), wherein it was following Beth’s departure that Pam stayed (52a). The fact that the high-scope interpretation is not available suggests that reduced clausal TACs must be interpreted relatively low on the verbal spine.

It is also telling to consider again briefly direct phrasal TACs like the one in (53).

(53)   Kim didn’t leave after dinner.
   a. afterP > ¬: ‘After dinner time, Kim didn’t leave.’
   b. ¬ > afterP: ‘Kim left, but it’s not the case that she did so after dinner time.’

This example presents an interesting contrast with the reduced clausal TAC above. Direct phrasal TACs are ambiguous with respect to sentential negation in the same way observed for full clausal TACs. This can be taken as further evidence that not all phrasal TACs are made equally. It also implicates the reduction mechanism in the restricted distribution of reduced clausal TACs.\footnote{This analysis leaves several questions unanswered and available space precludes engaging with those questions here. I would direct the reader to Overfelt 2018:sec. 2.3 for supplemental discussion.}

\subsection*{3.2 Alternative Reduction Analyses}

The analysis presented in the previous subsection proposed that phrasal TACs involve $\overline{\Lambda}$-movement of a remnant out of the elided small clause complement to a low-joined temporal connective. This is not the first analysis to propose that phrasal TACs are derived from a clausal source via ellipsis. We will look here at some alternatives made available in the literature with a focus on some issues they encounter and how the present proposal avoids them.\footnote{An anonymous reviewer points out that the data and analysis presented in the previous section share a number of similarities with what can be found in Yoshida 2013. Yoshida (2013) presents pairs of examples like those in (i), arguing that phrasal likePs are reduced from a clausal source.}

\begin{itemize}
\item[(i)]
\begin{itemize}
\item a. Michael must not dance like Fiona
\item b. Michael must not dance like Fiona danced.
\end{itemize}
\end{itemize}

Part of this argument includes the observation that it is possible to interpret modals and negation in a phrasal likeP,
3.2.1 Larson 1987

Larson (1987) suggests that reduced TACs represented by the string in (54a) arise from a derivation that circumvents an antecedent-contained deletion (ACD) configuration.

\[(54)\]

a. John [\[T \text{ arrived } \langle O_1 \text{ before Max } \langle T e \rangle \rangle]\]

b. [\[O_1 \text{ before Max } \langle T e \rangle\]_1 [John [\[T \text{ arrived } t_1 \] ]]

c. [\[O_1 \text{ before Max } \langle T \text{ arrived } t_1 \rangle\]_1 [John [\[T \text{ arrived } t_1 \] ]]

The TAC is generated with an T constituent containing an empty category, as in (54a). Resolving the identity of the empty category requires the application of Quantifier Raising (QR) shown in (54b). This places the TAC in a position outside of its containing I. In this position, the ellipsis site can be resolved through LF-copying of the root I-constituent into the TAC; see (54c). Though not stated explicitly in Larson 1987, the idea seems to be that the copied instance of the trace of the TAC comes to be bound by a covert operator O_1 within the TAC (see section 5.1).

The reader will find that the analysis that is ultimately presented in section 5 is quite similar to what is shown in (54). However, there are several reasons not to adopt this exact implementation. The first issue to observe with this analysis is that the ellipsis resolution process targets an I node, a non-phrasal constituent. This runs counter to what seems to be the modern consensus that ellipsis deals in phrasal constituents. The analysis of TAC-Stripping that was proposed in section 3.1, on the other hand, asserts ellipsis of a phrasal constituent.

Second, the analysis presented in (54) proposes both that the elided constituent contains I^0 and that the reduced TAC is interpreted at the level of IP, equivalently referred to as S in Larson 1987. These proposals are at odds with the data available in the previous section. Recall that we were lead to the conclusion that, in the case of TAC-Stripping, it is a constituent that is smaller than IP that is deleted. We were also lead to conclude that a TAC targeted by TAC-Stripping is interpreted relatively low on the verbal spine, and certainly lower than IP. These are observations that the analysis proposed in section 3.1 is designed to deliver.

but only when that likeP can be interpreted higher than these projections on the verbal spine, namely at TP. This leads to an analysis of phrasal likePs that involves movement of the remnant out of an elided TP. It is claimed that this TP can be elided under satisfaction of Merchant’s (2001) e-GIVENness with a TP or a VP when the latter option avoids antecedent-containment.

Choosing between the analysis in Yoshida 2013 and the analysis being presented, both for phrasal likePs and phrasal TACs, must be left for a future occasion. Although, it is worth keeping in mind that, alongside the assumption that phrasal likePs can only contain TPs, the primary motivations for the analysis in Yoshida (2013) include the observations that phrasal likePs can be interpreted at various positions on the verbal spine and that it is possible to interpret modals and negation in the deletion site. Section 3 argued that none of these are properties of reduced clausal TACs.
3.2.2 Thompson 2005

Thompson (2005) proposes an analysis of reduced TACs that avoids the issues of QR and traces. Ellipsis resolution involves LF-Copying, but the TAC is base-generated as a TP-adjunct, as in (55).

(55) a. John left before Bill
e

b.  

\[
\text{TP} \\
\text{TP} \quad \text{PP} \\
\text{DP} \quad \text{T} \quad \text{P}^0 \quad \text{TP} \\
\text{John} \quad \text{T}^0 \quad \text{AspP} \quad \text{before} \quad \text{DP} \quad e \\
\text{left} \quad \text{Bill}
\]

(adapted from Thompson 2005:77, (45))

Thompson (2005:77) suggests that the ellipsis site is resolved by “copying (the lower segment of) TP into the ellipsis site.” Copying the lower segment of the TP generates the representation in (56).

(56) John left [PP before [TP Bill [TP John left]]]

It is not clear that this would be a legitimate representation. Seeing as it leaves Bill uninterpreted as an argument in the embedded clause, it would not obviously generate the intended interpretation, which is that John left and this happened before Bill left. It seems that on this analysis it must be asserted instead that the root $T$ must be copied into the ellipsis site. Like Larson (1987), this analysis must assume ellipsis of a non-phrasal constituent and, for this reason, should be dispreferred to the analysis of TAC-Stripping being presented. We can add that this analysis also fails to reflect our findings regarding the size of the reduced TAC and its point of interpretation.

Another significant issue for both the analysis in Thompson 2005 and the analysis in Larson 1987 comes from the observation in section 2.1 that the remnant of a phrasal TAC may be ambiguous given a transitive predicate. This ambiguity is not expected if truncated TACs are derived only by ellipsis of an $I$-constituent as proposed by Larson (1987) or a $T$-constituent as required for Thompson (2005). No material other than what appears in the grammatical subject position or higher would be expected to survive ellipsis. However, this is an expected property in the analysis of phrasal TACs presented above. The interpreted grammatical role of the remnant is a consequence of its base-generated position within the elided clausal material.

Finally, the analysis in (55) admittedly presents a more simplified derivation for reduced TACs
relative to Larson 1987 and what will be presented in section 5.1. We will find, however, that there is significant explanatory power in asserting that TACs do undergo QR and leave behind traces.

3.2.3 Conjunction Reduction

The analysis presented in Larson (1987) is motivated in part by the idea that it is possible to think of TACs as counterparts to comparatives like earlier and later. This basic intuition can in fact be traced as far back as Geis (1970:ch.4), who noted a number of syntactic and interpretive similarities between these constructions. An alternative implementation of this idea could build from Lechner (2004), who argues that phrasal comparatives have a clausal source and are derived coordination configurations, as in (57).

(57)

The argumentation that Lechner (2004) provides for this derived conjunction analysis is based on the conclusion that comparative constructions can be targeted by Across-the-Board Movement, Gapping, Stripping (as a form of Gapping), and Right Node Raising. The reasoning is that these reduction processes only target conjunctions, therefore, comparative constructions at least can be conjunctions at a point in the derivation when these mechanisms apply.

A similar approach to phrasal TACs would reject the claim that they involve subordination. Instead, they would similarly be treated as (derived) coordinations that are possibly reduced via Gapping, Right Node Raising, or Across-the-Board Movement. As we will see presently, there are considerations that speak against this approach. TACs cannot be targeted by the full range of reduction mechanisms available to comparatives, they fail to display properties expected of coordinations, and the temporal connectives before and after show non-characteristic properties of comparatives.

Concerning the reduction mechanisms, it has been argued that Across-the-Board Movement and Right Node Raising do not exclusively appear in coordination configurations (see, for instance, Munn 1992 and Postal 1993, 1994 on parasitic gaps). On the other hand, Gapping has relatively un-
controversially been assumed to be impossible outside coordinations (Jackendoff 1971, Hankamer 1979). Therefore, the availability of Gapping seems to be the strongest argument for a coordination treatment of comparatives and potentially for TACs. However, as pointed out by Lobeck (1995) and Penka & von Stechow (2011), only a single remnant is possible within the TAC. Consider (58):

(58) a. Kim read the article and Sam read the book.
    b. Kim read the article earlier than Sam read the book.
    c. *Kim read the article before Sam read the book.

This paradigm can be taken to teach us two things. The first is that TACs do not tolerate Gapping (58c), unlike coordinations and comparatives. This is consistent with the claim that these phrasal TACs are derived from a clausal source given that they are subordination configurations (cf. Penka & von Stechow 2011:441). Second, following Lechner’s (2004) reasoning, the failure for Gapping to target TACs can be interpreted as evidence that TACs should not be treated on par with either coordination or comparative configurations.

Additional facts speak against equating TACs and coordinations, including their differing ability to appear clause-initially in (59).

(59) a. *And he read the magazine, Tim read the book.
    b. After he read the magazine, Tim read the book.

To the extent that phrasal TACs require treatment as coordinations, the expectation is that they, too, should resist appearing clause-initially. Instead, we find that phrasal TACs can appear clause-initially. This is shown in (60), which suggests that phrasal TACs are not (derived) coordinations.

(60) After the magazine, Tim read the book.

Moreover, if phrasal TACs required treatment as coordination, we would expect that it is not possible to extract from only the first conjunct. Assuming that the moved element does not come to bind a variable in the second conjunct, the result demonstrated by the clausal examples in (61) would be a violation of the Coordinate Structure Constraint (Ross 1967, Ruys 1992).

(61) a. *I know what Kim read x₁ and she read the magazine.
    b. I know what Kim read x₁ after she read the magazine.

This expectation is not borne out. The sentence in (62) shows that phrasal TACs behave like subordination structures with respect to extraction.
(62) I know what $x_1$ Kim read after the magazine.

Despite their actual and intuitive similarities, there is also reason to think that before and after are not counterparts to the comparatives earlier and later. For example, a seemingly ubiquitous property of comparatives is their ability to license negative polarity items (NPIs), like anyone in (63). However, it has been known at least since Geis 1970 that, while before licenses NPIs, after does not. The contrast is shown in (64) for both clausal and phrasal variants.

(63) a. Meg left later than anyone else (left).
   b. Bob ate earlier than anyone else (ate).

(64) a. *Meg left after anyone else (left).
   b. Bob ate before anyone else (ate).

To this we can add the asymmetry between after and before with respect to the their scope relative to sentential negation. Section 3.1.2 demonstrated that clausal afterPs may be interpreted either above or below sentential negation. It was observed in footnote 10, however, that clausal beforePs strongly resist being interpreted above sentential negation. Comparatives, on the other hand, are generally thought to be scopally inert with respect to negation (e.g., Heim 2000).

Finally, Geis (1970:143–146) observes what he refers to as the Verb-Verb Constraint, which describes the dispreference for mismatched verbs in the comparative and root clauses in (65).

(65) a. ??Joe left later than he ate.
   b. ??Joe left earlier than he ate.

(66) a. Joe left after he ate.
   b. Joe left before he ate.

No account is provided for this constraint. Although my intuition, and that of several linguists and non-linguists, is that (65) can be improved by placing a pitch accent on the verbs. This may be taken to suggest that (65) is a case of comparative subdeletion. Regardless, the relevant observation is that no such oddity arises in the TACs in (66). The verb of the root clause and TAC can mismatch without any particular prosodic licensing.

In sum, both clausal and phrasal TACs display properties indicating that they are syntactically distinct from more usual instances of comparatives and coordinations. These conclusions will guide the remainder of the paper as we attempt to account for the distribution of phrasal TACs under the analysis of TAC-Stripping presented in this section.\textsuperscript{13}

\textsuperscript{13}We are now in a position to comment on the remaining argument from Penka & von Stechow (2011) for a direct analysis of phrasal TACs in English. They point out that phrasal TACs cannot contain more than one constituent in addition to the temporal connective, as in (i).
4. The Eliminative Puzzle of TAC-Stripping

In this section we turn to constraints on the distribution of reduced clausal TACs. As we will see, their distribution can be described by the constraint in (4), repeated in (67).

(67) No Asymmetric Embedding

A TAC-Stripping site and its antecedent must be at the same level of embedding.

This constraint encompasses the idea that, given the analysis of TAC-Stripping, the interpretation of a reduced phrasal TAC cannot be resolved to any other predicate than the one it modifies. The next two subsections will establish this empirical generalization. The third subsection acknowledges the resemblance this constraint shares with observations made in the literature regarding Gapping and various Bare Argument Ellipses. I will argue that available approaches for those constructions are not suited for TACs, given their resistance to being treated as coordinations.

4.1 The Distribution of Clausal Temporal Adverbs

As is commonly thought to be the case for other adjuncts, utterance-final clausal TACs may be ambiguous with respect to their point of adjunction on the clausal spine in multi-clausal constructions. The string is (68) provides a relevant example.

(68) Kim heard that Sue left after Joe left.

On one bracketing of the string in (68), the TAC after Joe left is a constituent of the embedded clause. This constituency generates an interpretation whereby the TAC modifies the event of Joe leaving. This is shown in (69), which we will refer to as the embedded interpretation.

(i) *Mary drank the beer after Peter drank the whiskey. (adapted from Penka & von Stechow 2011:441, (27a))

The argument presented in Penka & von Stechow (2011) is that this contrasts with phrasal comparatives, which do allow multiple remnants or, in other terms, permit Gapping (Lobeck 1995, Lechner 2004). On the reduction account of phrasal TACs being proposed, this should follow from whatever disallows Gapping in subordination structures (sec. 3.2.3). To the extent that Pseudo-gapping is suspected to generate additional remnants (e.g., Takahashi 2004), we can understand why it fails to do so in reduced TACs. Object Shift could be assumed to be too local to escape the ellipsis operation. Assuming that the remnant of TAC-Stripping is generated by HNPS, a second remnant will also be ruled out by whatever is responsible for the constraint against multiple HNPS; see (ii).

(ii) a. Kim gave her friends $x_1$ this morning — some coffee$_1$.
   b. *Kim gave $y_2$ $x_1$ this morning — her friends$_2$ some coffee$_1$. 
(69) *Embedded interpretation*

Kim heard [CP that Sue left after Joe left ]

‘Kim heard that, after Joe left, Sue left.’

On an alternative bracketing, the TAC is a constituent of the embedding clause. The interpretation is one where the TAC modifies the event of Kim hearing about the fact regarding Sue, as shown by (70). We will refer to this as the *matrix interpretation*.

(70) *Matrix interpretation*

Kim heard [CP that Sue left ] after Joe left.

‘After Joe left, Kim heard that Sue left.’

That these interpretations indeed correspond to the proposed bracketings is supported by basic constituency diagnostics. Replacing the embedded clause with a proform would presumably remove the structure that hosts the clausal TAC and the embedded interpretation should become unavailable. This expectation is realized in the following example.

(71) Kim heard it after Joe left.

≠ ‘Kim heard that, after Joe left, Sue left.’

= ‘After Joe left, Kim heard that Sue left.’

A structural account of the observed ambiguity also predicts a correlation between the interpretation of the TAC and bound-variable interpretations of pronouns inside the TAC. The matrix reading of the TAC should not permit a variable in the TAC to be bound by the embedded subject on account of being interpreted outside the scope of the embedded subject. The example in (72) is provided to show that this prediction is borne out.

(72) Kim heard that no one\textsubscript{1} left after his\textsubscript{1} boss left.

a. = ‘Kim heard that, for no person $x$, after $x$’s boss left, $x$ left.’

b. ≠ ‘After $x$’s boss left, Kim heard that, for no person $x$, $x$ left.’

We are also led to the expectation on this account that either reading will be available if it is the matrix subject that binds a pronoun in the TAC. The example in (73) is provided to show that this prediction is borne out.
(73) No one$_1$ heard that Kim left after his$_1$ boss left.
    a. = ‘For no person $x$, $x$ heard that, after $x$’s boss left, Kim left.’
    b. = ‘For no person $x$, after $x$’s boss left, $x$ heard that Kim left.’

These observations support what is likely to be the unsurprising conclusion that the height of
adjunction of a TAC determines its modification relationship.

4.2 The Distribution of Reduced Temporal Adverbs

We have already seen one way in which the distribution of reduced clausal TACs differs from their
full clausal counterparts in section 3.1.2. We will see here that the non-overlapping distribution of
reduced and unreduced TACs is even more general.

The previous subsection considered strings like in (74a), observing that the clausal TAC is
ambiguous with respect to its point of adjunction on the verbal spine. The string in (74b) differs
minimally in that it now contains a phrasal TAC.

(74) a. Kim heard that Sue left after Joe left.
    b. Kim heard that Sue left after Joe.

The string in (74b) is not ambiguous in the same way as its counterpart in (74a). The phrasal TAC
can be paired with the embedded interpretation, which we expect to arise from the bracketing in
(75) along with the application of TAC-Stripping that is illustrated.$^{14}$

(75) Kim heard $\text{[CP (that) Sue left after Joe } \langle \text{vP left } \rangle]$  
    = ‘Kim heard that, after Joe left, Sue left.’

Missing from this string, however, is the matrix-level interpretation that is illustrated in (76).

(76) *Kim heard $\text{[CP (that) Sue left ] after Joe } \langle \text{vP left } \rangle$.
    $\neq$ ‘After Joe left, Kim heard that Sue left.’

This is not to say that a phrasal TAC must adjoin to an embedded position or that TAC-Stripping
cannot target an embedded TAC. As shown in (77), matrix-level modification of a phrasal TAC is
possible when the meaning of the TAC-Stripping site is resolved to the matrix predicate.

$^{14}$Here and in the following sections I will represent the ellipsis site in these examples with the finite form of the
predicate, contra the claims made in section 3. This is purely to ease the comparison of these examples with their
non-reduced counterparts.
(77) Kim heard \([CP (that) Sue left] \) after Joe \(\langle vP \text{ heard that Sue left} \rangle \).

\[= \text{‘After Joe heard that Sue left, Kim heard that Sue left.’}\]

The contrast between the examples in (76) and (77) is rather telling. It seems to suggest that a matrix-adjointed adjoined TAC can be targeted for TAC-Stripping, but the TAC-Stripping site is necessarily resolved to the clause that it modifies. It is possible to provide a similar description of the contrast between (75) above and the example in (78) below.

(78) *Kim heard \([CP (that) Sue left after Joe \langle vP \text{ heard that Sue left} \rangle \]).

\[\neq \text{‘Kim heard that, after Joe heard that Sue left, Sue left.’}\]

The intended interpretation of this string, which is unavailable, is one in which the TAC modifies the embedded predicate but the TAC-Stripping site is resolved to the matrix predicate.

That this is the correct description of the facts is corroborated by the example in (79).

(79) Kim heard \([CP (that) Sue left after Joe \langle vP \text{ heard that Sue left} \rangle \].

\[= \text{‘Kim heard that, after Joe heard that Sue left, Sue left.’}\]

This string provides the clausal variant of the example in (78) and is grammatical on the intended interpretation. This suggests that it is not the bracketing itself that results in the ungrammaticality observed in (78). Instead, it is the phrasal TAC—and presumably the particular application of TAC-Stripping—that is disallowed under this bracketing.

4.3 Section Summary and Discussion

The discussion in the previous two subsections is summarized by Table 1, which shows the available interpretation of a TAC-Stripping site as a function of the point of adjunction of the reduced TAC. A way to understand these facts, which is represented by the No Asymmetric Embedding condition, is that a TAC-Stripping site in a reduced TAC is necessarily resolved to the vP that it directly modifies.

Table 1: Source of antecedent for TAC-Stripping as a function of adjunction site.
This behavior is reminiscent in certain ways to effects observed for Gapping and Stripping.\footnote{It is possibly tempting to analogize the data investigated in this section also with the familiar constraints against embedding a Gapping or Stripping site under another predicate (Hankamer 1979, Lobeck 1995, Johnson 2019), which have been counter-exemplified by Weir (2014a) and Wurmbrand (2017). Space precludes providing a full discussion of such examples, but the reader might confirm that examples like (i) are at least consistent with the analysis in section 5.3.}

Johnson (2009) proposes that an inability to embed the antecedent of Gapping is a property one would expect if Gapping involved coordination of vPs and Across-the-Board (ATB) extraction of VPs, a proposal given slightly more substance in Johnson 2019. In a response to Johnson (2009), Toosarvandani (2016) proposes that a requirement for conjoined vPs to have parallel focus structures is the source of Gapping’s apparent inability to identify an embedded antecedent.

Setting the precise details of these proposals aside, neither of them is suited to be applied to constraints on TACs. Recall from section 3.2.3 that reduced clausal TACs are not amenable to treatment as coordination structures. Thus, any constraint on conjoined vPs, as in Toosarvandani (2016) will not be applicable. These observations, if correct, also preclude an analysis of phrasal TACs that employs VP extraction, ATB or otherwise, as in Johnson (2009). Postal (1993) catalogs a significant amount of evidence that ATB extraction is not possible in subordination structures and, moreover, that only nominal constituents can license parasitic gaps in such structures.

An alternative idea entertained by Johnson (2019) is to make these constraints follow from models of the identity and recoverability conditions on ellipsis that require antecedence by a possibly implicit question meaning in the discourse, such as can be found in AnderBois 2011 and Barros 2014 for sluicing and Weir 2014a for fragment answers, which arguably are a species of Bare Argument Ellipsis (cf. Progovac 2013). Again, details aside, there is reason to disprefer this type of account for TAC-Stripping. Speaking in terms of the Question Under Discussion (QUD) for concreteness (Büring 2003, Roberts 2012), diagnostics presented in Tonhauser 2012 suggest that the content of TACs is not-at-issue with respect to the QUD.\footnote{It is worth noting that the claim is not that the TAC as a whole cannot be or be part of some larger at-issue-content. That this is possible is reflected by the fact that a full or reduced clausal TAC is one way to provide an answer to a question like in (i).}

For example, Tonhauser (2012:sec. 3.2) proposes that QUD-not-at-issue content cannot solely
address the QUD. In (80), the QUD is proffered explicitly. Under standard theories of question-answer congruence (e.g., Rooth 1992a, Roberts 2012), a felicitous answer would have the form of a proposition in \( \{ p : x \text{ left} \mid x \in D_e \} \). A proposition of the appropriate shape is provided in the content of the TAC by B, but it fails to felicitously provide this as an answer. In comparison, when an appropriate answer appears in the root clause, as is the case in the response from \( B' \), the utterance provides a felicitous answer, modulo Quantity and Relevance implicatures perhaps.

(80)  
A: Who left?  
B: #Tom started reading before Sue left.  
\( B' \): ?Sue left before Tom started reading.

In a related diagnostic, Tonhauser (2012:sec. 3.3) proposes that not-at-issue content cannot determine the relevant set of alternatives for the QUD. The polar question in (81) cannot be interpreted as a request for answers of the form \( \{ \text{Sue left}, \text{Sue didn’t leave} \} \). This is evidenced by the infelicity of providing a positive answer with the corresponding positive alternative, as done by B. The response from \( B' \) shows that the content of the root clause, on the other hand, can felicitously provide the form of the alternatives for the question.

(81)  
A: Did Tom start reading before Sue left?  
B: #Yes, she left.  
\( B' \): ?Yes, he started reading.

These differences shown by the content of a TAC relative to the content of the root clause suggest that the content of a TAC has a different status in the discourse. Specifically, the content of a TAC is QUD-not-at-issue content.\(^{17}\) Thus, it is not clear that defining identity and recoverability conditions on TAC-Stripping that requires anaphoricity to a salient question meaning is a desirable way of modeling ellipsis here. This in turn casts doubt on the ability for such a condition to derive the No Asymmetric Embedding condition. Therefore, the following section will turn to providing an alternative analysis of these observations.

5. Ellipsis Bleeds Phrase Structure Representations

The analysis presented in this section attempts to attribute the No Asymmetric Embedding condition to the ability to satisfy an identity requirement on ellipsis. This account builds on what is

\(^{17}\)Following the discussion in Simons et al. 2010 this could be seen as another way of saying that the content of a TAC is “softly” presupposed (e.g., Abrusán 2016). This is a claim that can be traced back to Hooper & Thompson (1973), who cite Keenan (1971) for the same observation.
found in Takahashi 2008. However, as we will come to see, the accounts generate different predictions which ultimately favor the approach presented here. I will start by making more explicit the proposed treatment of TACs. I will then introduce the identity condition on ellipsis to be adopted and demonstrate its use in vanilla instances of TAC-Stripping. The remainder of this section shows how these assumptions correctly rule out those instances of TAC-Stripping that violate the No Asymmetric Embedding condition.

5.1 TACs and the Identity Condition on Ellipsis

The analysis to follow capitalizes on a more articulated treatment of TACs proposed by Geis (1970). Geis observed that certain TACs, including those introduced by before and after, are potentially ambiguous with respect to the events they order. The example in (82), for instance, might order Joan’s leaving-time before Harry’s telling-time (82a) or before the leaving-time that Harry provided (82b).

(82) Joan left [beforeP before λ1 Harry told t₁ [ her to leave t₁ ]].

a. ‘Joan left before t such that at t Harry told her to leave.’

b. ‘Joan left before t such that Harry told her to leave at t.’ (Geis 1970:127, (42))

I will refer to this as the Geis-ambiguity. For Geis (1970), following similar suggestions by Ross (1964), this ambiguity revealed that TACs are effectively relative clauses for unexpressed nominal constituents. We will take a similar path and model this ambiguity by asserting the presence of a null-operator chain within the TAC, as in Larson 1990. This operator is base-generated local to the predicate it modifies, moves to the edge of the clause embedded in the TAC, and leaves behind a variable (tn). This is sketched for each interpretation of (82).

Among the reasons to think that these examples are derived via movement is the sensitivity of the Geis-ambiguity to the presence of island boundaries, as pointed out by Geis (1970). The example in (83) is similar to (82) but now separates the temporal connective before from the predicate leave by a Complex-NP boundary.

(83) Joan left [beforeP before λ1 Harry told t₁ her of [ his desire [ for her to leave t₁ ]]].

a. = ‘Kim left before t such that at t Harry told her of his desire for her to leave.’

b. ≠ ‘Kim left before t such that Harry told her of his desire for her to leave at t.’ (Geis 1970:129, (55))

While the sentence in (83) has an interpretation where Joan left before the time at which Harry
expressed his desire, it lacks an interpretation whereby Joan left before the time for her to leave that Harry desired. In other words, the embedded interpretation is missing. This can be understood as an effect of a Complex-NP Constraint violation induced by movement of the postulated operator.

Regarding the base-position of the temporal operator, Takahashi (2008) asserts that it is low enough on the verbal spine to be contained in the constituent targeted by VP-Ellipsis, as in (84).\[^{18}\]

\[(84)\quad \text{Sue left } [\text{afterP after } \lambda l \text{ Joe did (} \text{leave} t_1 \text{) }]. \]

Without saying more it is not clear that ellipsis should be possible in this example. It seems to be a condition on ellipsis that variables in the ellipsis and antecedent sites must be bound from parallel positions or otherwise co-referent in the case that both are free ((NP) Parallelism; Sag 1976, Heim 1997, Fox 2000, though see Roelofsen 2010.) However, the elided constituent in this representation contains a bound variable that has no correlate in any available antecedent.\[^{19}\] To address this issue, Takahashi (2008) adopts the proposal, made independently by Larson (1987) and also Fox & Nissenbaum (2003), that TACs themselves undergo QR within their root clause.

\[(85)\quad [\text{afterP after } \lambda l \text{ Joe did (} \text{leave} t_1 \text{) }] \lambda 2 \text{ Sue [ left } t_2 \text{] }\]

The effect, shown in (86), is the introduction of a parallel temporal variable in the antecedent.

Incorporating these pieces into our account of phrasal TACs gives the representation in (86). The TAC undergoes an instance of covert movement that targets some functional projection (FP) outside the root vP. In accordance with the data presented in section 3.1.2, we can assume that this is still a relatively low position on the verbal spine.

---

\[^{18}\]It is this assertion that we will take issue with in section 6, arguing that the base-position of the temporal operator is inside the constituent targeted by TAC-Stripping but is outside the smaller constituent targeted by VP-Ellipsis.

\[^{19}\]An anonymous reviewer rightly reminds that the phenomenon of sprouting, notably discussed by Chung et al. (1995), might equally lead one to suspect that ellipsis should be possible in (84). For recent discussions of how to reconcile sprouting with a condition like NP Parallelism see Thoms 2015 and Kotek & Barros 2019.
To understand how ellipsis is permitted in this representation we will adopt the focus-based semantic identity condition in (87). This is a slightly modified version of what can be found in Rooth 1992a and Takahashi & Fox 2005.

(87) Ellipsis of some XP is permitted only if:

i.) there is a parallelism domain (PD) that contains XP,

ii.) there is an antecedent constituent (AC), and

iii.) $[[AC]]^o \in [[PD]]^f$ for any variable assignment function $g$.

In prose, (87) says that a constituent (XP) may be elided on the condition that it is contained within some constituent (PD) whose focus semantic value, given any assignment function $g$, contains as a member the ordinary semantic value of some antecedent constituent (AC). As per the discussion in 4.3, we are assuming that the AC for TAC-Stripping must be found in the overt syntax because the content of TACs cannot obviously be anaphoric to implicit question meanings. The focus semantic value of a constituent is the set of alternatives that are derived by replacing focus marked constituents—which includes at least the remnant in a reduced clausal TAC—with their type-matching alternatives.

In (88) we can see how to apply the identity condition in (87) to the example in (86).

(88) a. $[[AC]]^o = \lambda t. \text{Kim met Sue at } t$

b. $[[PD]]^f = \{ p : \lambda t. \text{Kim met } x \text{ at } t \mid x \in D_e \}$

c. $[[AC]]^o \in [[PD]]^f$ for any $g$, ellipsis is permitted.

Given the presence of bound variables in the elided $\langle vP \rangle$, it will be necessary to define the PD as
the node directly dominating the binder $\lambda 2$, which contains the binders for both elided variables. Only this will guarantee that an AC can be identified that, under any variable assignment function, is a member of the computed alternative-set. The constituent that contains the binder $\lambda 1$ for the trace of the TAC provides an appropriate AC. Therefore, with respect to the identity condition on ellipsis, ellipsis of $\langle \text{vP} \rangle$ is permitted and a TAC-Stripping configuration emerges.

5.2 Antecedent-contained TAC-Stripping

We are now prepared to turn to the analysis of the No Asymmetric Embedding condition in (67) and visualized in Table 1. Let us start by considering the interpretations available to phrasal TACs that are adjoined to embedded clauses.

(89) a. *Kim heard [CP (that) Sue left after Joe $\langle \text{vP heard that Sue left} \rangle$]

As per the No Asymmetric Embedding condition, the interpretation of the reduced TAC in (89) cannot be resolved to the matrix predicate.
Given an ellipsis-based analysis of phrasal TACs, the ungrammaticality of this example can be understood straightforwardly as an instance of irreparable antecedent-containment that precludes the possibility of ellipsis. The general finite-clause boundedness of QR means the phrasal TAC in (91) will be trapped in the embedded clause and unable to escape the attempted antecedent. As (90) shows, the calculation of identity is expected to fail.

(90)  
a. \[ \llbracket \text{AC} \rrbracket^o = \text{Kim heard that Sue left at some } t \text{ after Joe heard that Sue left at } t' \]
b. \[ \llbracket \text{PD} \rrbracket^f = \{ p : \lambda t. x \text{ hear Sue leave at } t \mid x \in D_e \} \]
c. \[ \llbracket \text{AC} \rrbracket^o \notin \llbracket \text{PD} \rrbracket^f \text{ for any } g, \text{ ellipsis is not permitted.} \]

The intended AC is not something that can be derived by replacing focused marked elements in the PD with their alternatives.

The available interpretation for the string under consideration is one in which the ellipsis site is resolved to the embedded predicate. The relevant example is provided again in (92) along with a partial representation that includes just the embedded clause.

(91)  
a. \text{Kim heard } \llbracket \text{CP (that) Sue left after Joe } \langle \text{vP left} \rangle \rrbracket 

\[ \llbracket \text{CP} \rrbracket = \text{CP} \]
\[ \llbracket \text{that} \rrbracket = \text{that} \]
\[ \llbracket \text{IP} \rrbracket = \text{IP} \]
\[ \llbracket \text{Sue} \rrbracket = \text{Sue} \]
\[ \llbracket \text{t}^0 \rrbracket = \text{t}^0 \]
\[ \llbracket \text{FP} \rrbracket = \text{FP} \]
\[ \llbracket \text{AC} \rrbracket = \text{AC} \]
\[ \llbracket \text{afterP} \rrbracket = \text{afterP} \]
\[ \llbracket \text{vP} \rrbracket = \text{vP} \]
\[ \llbracket \text{v}^0 \rrbracket = \text{v}^0 \]
\[ \llbracket \text{VP} \rrbracket = \text{VP} \]
\[ \llbracket \text{Sue left} \rrbracket = \text{Sue left} \]
\[ \llbracket \text{PD} \rrbracket = \text{PD} \]
\[ \llbracket \text{Joe} \rrbracket = \text{Joe} \]
\[ \llbracket \text{vP} \rrbracket = \text{vP} \]

The present analysis predicts the contrast on account of the fact that it is possible to identify an AC in this representation that does not contain the PD containing the elided constituent. The calculation of the identity for the purpose of ellipsis is provided in (92).
5.3 Non-Parallel Variable Binding

We turn now to the interpretations available to phrasal TACs that are adjoined to the matrix clause. In (93) is the proposed representation for the attempt to modify the matrix vP with a phrasal TAC and resolve the ellipsis site to an embedded vP.

(93)  a. *Kim heard \([CP \text{ (that) Sue had left }]\) after Joe \(\text{⟨vP leave⟩}\)

b. 

![Tree diagram for (93)]

The ungrammaticality of (93) is not obviously expected. On any theory of ellipsis the ungrammaticality could not be attributed to antecedent-containment of the ellipsis site or a constituent.
containing the ellipsis. As noted in the previous section, several analyses have attempted to tie similar effects in other domains to something besides the ability to permit ellipsis. I propose that, in the case of reduced clausal TACs, the ungrammaticality being observed represents a failure to satisfy the identity condition on ellipsis. What does the work here—similar to Takahashi 2008—is the temporal operator-variable relationship that we have seen is present in the TAC. Because the TAC serves to modify the matrix predicate, it will be generated in a position adjoined to a projection of the matrix predicate. The relevant effect is that there will be no parallel temporal operator-variable relationship in the complement clause from which the AC is pulled.

It is the absence of this operator-variable chain that disrupts the calculation of identity. The necessary PD for licensing ellipsis will be the same as we just saw above. An antecedent must be found for a constituent that contains the binder for the trace of the temporal operator. Because of the absence of a parallel operator-variable relationship in the complement clause, however, there is no appropriate AC in the representation provided in (93). As shown in (94), the nearest possible AC that can be identified is not a member of the set of focus alternatives derived from the PD for the elided constituent.

(94)  a. $\llbracket AC \rrbracket^o$ = Sue left
     b. $\llbracket PD \rrbracket^f$ = $\{ p : \lambda t. x \text{ leave at } t \mid x \in D_e \}$
     c. $\llbracket AC \rrbracket^o \notin \llbracket PD \rrbracket^f$ for any $g$, ellipsis is not permitted.

Again, the linear string under consideration here is not unavailable. As per No Asymmetric Embedding, the available interpretation is one in which the ellipsis site is resolved to the matrix predicate. This example with its representation is provided in (95).
The PD for which an appropriate AC must be found must still contain the binder for the elided temporal variable. However, the focus alternatives derived from this constituent, given the shape of the elided content, will now contain as a member the AC that is indicated in (95). As shown in (96), it is determined that ellipsis is permitted on the intended interpretation.

At this point we can appreciate a specific prediction that this analysis makes with respect to the effect of TAC-Stripping on the Geis-ambiguity. The requirement for parallel operator-variable binding that the identity condition in (87) enforces leads us to expect that TAC-Stripping will also have an eliminative effect on the point of adjunction for the temporal operator inside the TAC and, therefore, on its possible interpretations. More plainly, this analysis predicts that the temporal operator cannot be generated as a modifier of the embedded leaving-event within the TAC in (95). As shown below in (97), the resulting non-parallel binding chains in the PD and AC are expected to disrupt the adopted identity condition.
This prediction is borne out. To see this, let us first convince ourselves that we observe the Geis-
ambiguity in the kind of TAC under consideration. This is demonstrated in the slightly simplified
example in (98) wherein Sue’s leaving-time is ordered after either the time at which Joe heard
something or the time of Sue’s leaving that Joe heard about.

(98) Sue left \( \text{after} \lambda \text{Joe heard } t_1 \) \( [\text{CP (that) she left } t_1] \).

a. = ‘Sue left after \( t \) such that Joe heard at \( t \) that she left.’
b. = ‘Sue left after \( t \) such that Joe heard at \( t \) that she left at \( t \).

Consider again the example in (95), which is provided below with the relevant interpretations.

(99) Kim heard \( [\text{CP (that) Sue left }] \) \( [\text{after} \lambda \text{Joe did } (\text{vp heard } t_1 \text{[cp that she left } t_1])] \).

a. = ‘After Joe heard at \( t \) that Sue left, Kim heard at \( t’\) that Sue left.’
b. ≠ ‘After Joe heard that Sue left at \( t \), Kim heard at \( t’\) that Sue left.’

As indicated, the embedded interpretation for the temporal operator in the reduced TAC in (99)
is unavailable, as expected. This supports the proposed analysis of TAC-Stripping as an instance
of ellipsis. It also provides further support for the treatment of the No Asymmetric Embedding
condition as a symptom of impermissible ellipsis caused by non-parallel temporal operator chains.

6. The VP-Ellipsis Puzzle

Having taken an ellipsis approach to accounting for the restricted distribution of reduced TACs, we
turn now to a second, yet still familiar puzzle. As has been observed previously, VP-Ellipsis (VPE)
is not subject to the No Asymmetric Embedding condition. This distinguishes it from Gapping and
Stripping, and now from the TAC-Stripping operation that has been identified in phrasal TACs. It
is also not obviously a result that is expected from the analysis presented above or the analysis of
TACs presented in Takahashi 2008. After establishing this extended paradigm, I will argue that the
data reflect the fact that VPE targets a smaller constituent for ellipsis than does TAC-Stripping.

6.1 The Extended Paradigm

Let us consider first the interpretations available to a VPE site inside of a TAC that is adjoined to
an embedded clause.

(100) *Kim heard \( [\text{cp (that) Sue left }] \) \( \text{after Joe did } (\text{hear that Sue left}) \).

‘Kim heard that, after Joe heard that Sue left, Sue left.’
Reduced Temporal Adverbs

(101) Kim heard \([_{CP}(that) \text{ Sue left after Joe did } \langle \text{ left } \rangle]\).

‘Kim heard that, after Joe left, Sue left.’

As (100) shows, this configuration does not allow the VPE site to be resolved to the matrix predicate. It is possible, on the other hand, for the VPE site to be resolved to the embedded predicate, as in (101). This pattern mirrors what we saw in the previous section for TAC-Stripping and is not necessarily a surprising finding. The structure and interpretation in (100) is expected to be unavailable as another instance of irreparable antecedent-containment. If, on the other hand, an antecedent is pulled from the embedded predicate, as in (101), it should be possible avoid antecedent-containment and satisfy the identity condition on ellipsis.

The puzzle arises from the observation that a TAC adjoined to the matrix clause allows for a wider range of interpretations for a VPE site than we observed for a TAC-Stripping site. The relevant data points are provided below.

(102) Kim heard \([_{CP}(that) \text{ Sue left after Joe did } \langle \text{ hear that Sue left } \rangle]\).

‘After Joe heard that Sue left, Kim heard that Sue left.’

(103) Kim heard \([_{CP}(that) \text{ Sue left after Joe did } \langle \text{ left } \rangle]\).

‘After Joe left, Kim heard that Sue left.’

In (102) we see that the VPE site in this configuration can be resolved to the matrix predicate, which we also saw is possible in the context of TAC-Stripping. It is the grammaticality of examples like (103) that distinguish VPE from TAC-Stripping. In this example, the VPE site is contained in a TAC adjoined to the matrix clause and is resolved to the embedded predicate. The state of affairs is summarized in Table 2.

</table>

Table 2: Source of the antecedent for TAC-Stripping and VP-Ellipsis as a function of adjunction.

As pointed out above, the similarities between TAC-Stripping and VPE in embedded environments are expected and understood under an ellipsis-based account of these phenomena. What is unexpected is the ability for a VPE site in a matrix-modifying TAC to find an embedded antecedent. Recall that section 5.3 blocked this possibility in the context of TAC-Stripping by asserting that the presence of a temporal operator chain in the TAC, which is not paralleled by a similar relationship
Reduced Temporal Adverbs

in the embedded clause, precludes the identification of an appropriate AC. The same should be true in the context of VPE if, as suggested by Takahashi (2008), VPE also targets a constituent that contains the trace of the temporal operator in the TAC.

I will argue in what follows that we should no longer maintain the idea that the VPE site contains the trace of the temporal operator variable. The effect we will see is that, in the context of VPE, it is possible to search for a smaller AC, which the embedded clause is able to provide.

6.2 VP-Ellipsis v. TAC-Stripping

The asymmetry identified above can be made to follow, I argue, from the assertion that VPE is ellipsis of a smaller constituent than what is elided in TAC-Stripping. The basic idea finds support from a few additional asymmetries between the two ellipsis operations.

The first is relatively familiar from the recent literature regarding the size of VPE relative to other instances of ellipsis (e.g., Merchant 2013). The voice feature that is interpreted in a VPE site can differ, under certain circumstances, from the voice feature that is present in the antecedent constituent. Representative examples are provided in (104).

(104) a. ?The photos must be found before the police do {\text{\textit{VP find them}}}. 
b. ?The camera can still be used after the photographer does {\text{\textit{VP use it}}}.

In minimally differing examples that involve TAC-Stripping in (105), the same kind of mismatch is not tolerated to the same degree.

(105) a. *The photos must be found before the police_1 {\text{\textit{VP x find them}}}. 
b. *The camera can still be used after the photographer_1 {\text{\textit{VP x uses it}}}.

The contrast can be taken to indicate a difference in the size of the elided constituent. As Merchant (2013) suggests, VPE elides a constituent below the head responsible for the voice properties of a predicate. Thus, the voice features in the root clause predicate and the TAC are not subject to any kind of identity constraint and can vary in the way shown above. TAC-Stripping, on the other hand, we can assert is ellipsis of a constituent that does contain the relevant voice head. Therefore, the TAC-Stripping site must find an antecedent with an identical value for voice.

An anonymous reviewer provides an argument in a similar spirit that is based on discussion from Sailor (2014:sec. 1.4.2). The relevant observation, provided in (106), is that VPE inside of a TAC permits a strict interpretation when provided a reflexive antecedent VP.\footnote{This notably contrasts with VPE in coordinations which does not so readily permit sloppy interpretations, as shown in Hestvik 1995. See Sailor 2014 for a discussion of the full paradigm.}
(106) Lea will slap herself before Jane will.
   a. sloppy : ‘Lea will slap herself before Jane will slap herself.’
   b. strict : ‘Lea will slap herself before Jane will slap Lea.’

For Sailor (2014), building upon work by Ahn (2011), this can be seen as a product of the size of the constituent targeted by VPE. Asserting that reflexivity is encoded on a low functional head, namely the same head that encodes voice, it is because VPE in (106) targets a constituent below this head that a mismatch in reflexivity is possible. This mismatch gives rise to the strict interpretation. To the extent that TAC-Stripping is deletion of a constituent larger than that targeted by VPE and includes the head that encodes voice/reflexivity, then TAC-Stripping should disallow analogous strict interpretations. The reviewer provides example (107) to show this prediction borne out.

(107) Mary slapped herself before Sue.
   a. sloppy : ‘Mary slapped herself before Sue slapped herself.’
   b. *strict : ‘Mary slapped herself before Sue slapped Mary.’

Finally, note that when both the antecedent and ellipsis site are in the passive voice, as in (108), the passive auxiliary can escape VPE.

(108) a. The photos must be found before the documents must (be) ⟨vP found⟩.
   b. The trash should be emptied after the recycling should (be) ⟨vP emptied⟩.

This can be taken to reveal that VPE may in fact target various different kinds of constituents, including one that does not contain the passive auxiliary (e.g., Sailor 2014). However, we do not find the same kind of variability with TAC-Stripping. The examples in (109) show that it is not possible for the passive auxiliary to escape a TAC-Stripping site.

(109) a. The photos must be found before the documents (*being) ⟨vP found⟩.
   b. The recycling should be emptied after the trash (*being) ⟨vP emptied⟩.

The contrasts above can be understood by modeling VPE and TAC-Stripping as ellipsis operations that target different sized constituents, as shown in (110) and (111).
TAC-Stripping is intended to be ellipsis of the argument structure of the predicate, the functional structure that introduces voice/reflexivity, the trace of the temporal operator, and possibly other aspectual projections below $I^0$. Following Merchant (2013) and Sailor (2014), VPE inside a TAC is ellipsis of the argument structure of the predicate, possibly to the exclusion of the functional structure that introduces voice/reflexivity, but necessarily to the exclusion of the trace of the temporal operator.\(^{21}\)

6.3 The Puzzle Solved

Most relevant for the puzzle at hand is the assertion that VPE is ellipsis of a constituent that does not contain the trace of the temporal operator. Given our identity condition on ellipsis in (87), not including the trace of the temporal operator in the VPE site makes it possible to search for a smaller AC than is necessary for TAC-Stripping. This is because, in the case of VPE, there will be no bound variables in the ellipsis site.

To see this, consider the representation for the case of a matrix-joined TAC with a VPE site resolved to the matrix predicate. This is provided in (112) and should be contrasted with (93).

\(^{21}\)Providing an analysis of the difference between TAC-Stripping and VPE that is consistent with all of the properties of VPE identified by Sailor (2014) is beyond the scope of this manuscript. Although, as an anonymous reviewer notes, it is crucial to the analysis below that even the largest instantiation of VPE that is possible in TACs not does not include the trace of the temporal operator.
(112) a. Kim heard [CP (that) Sue [VP left]] after Joe did [VP left]

b. 

As argued in section 6.2, VPE is ellipsis of a constituent smaller than the constituent that contains the trace of the temporal operator. This means that it will not be necessary to identify a PD any larger than the deleted constituent. Because the deleted constituent does not have to find an AC with a trace of a temporal operator, the embedded VP now provides a possible antecedent. As shown in (113), the result is that ellipsis is permitted in this representation and the sentence is grammatical.\textsuperscript{22}

\begin{itemize}
\item[(113)] a. $\llbracket AC \rrbracket^o = \text{Sue left}$
\item b. $\llbracket PD \rrbracket^f = \{ p : x \text{ left} \mid x \in D_e \}$
\item c. $\llbracket AC \rrbracket^o \in \llbracket PD \rrbracket^f$ for any $g$, ellipsis is permitted.
\end{itemize}

In sum, the wider distribution of VPE relative to TAC-Stripping can be understood as a function of the ability to satisfy the identity condition on ellipsis given the additional claim that both phenomena involve ellipsis but target different sized constituents.\textsuperscript{23}

\textsuperscript{22}This requires that neither A-movement nor $X^0$-movement introduce variables that require extending the PD (Messick & Thoms 2016, Overfelt 2020, cf. Hartman 2011).

\textsuperscript{23}One should wonder why VPE—be it big VPE or the preferred small VPE according Sailor (2014)—is not a
7. Conclusion

This manuscript has argued that phrasal TACs can be derived by an ellipsis operation that targets the truncated complement in a low-adjointed beforeP or afterP. It was argued that the elided constituent is larger than what is targeted in instances of VP-Ellipsis, but smaller than the elided constituent in genuine Stripping. I referred to this constituent as vP. The single remnant in a phrasal TAC was argued to be generated by $\overline{A}$-movement to a focus position outside the elided constituent, as Depiante (2000) has proposed for canonical Stripping.

We also adopted an articulated syntax-semantics mapping that involved covert movement of and within the TAC (Geis 1970, Larson 1987, Takahashi 2008). These pieces together provided a way to account for the observation that reduced TACs have a more constrained distribution than either their full clausal counterparts or TACs containing VPE. Put simply, trying to identify an antecedent that is a constituent other than the vP that the phrasal TAC directly modifies will necessarily fail. This was the result of creating an irreparable antecedent-containment configuration (section 5.2) or requesting an antecedent that lacks a binding relationship parallel to the temporal operator-variable relationship in the ellipsis site (section 5.3). The differing distribution of TAC-Stripping and VPE was argued to be an effect of VPE eliding a smaller constituent that does not include the TAC’s temporal operator-variable relationship. This made it possible in the case of VPE, but not in TAC-Stripping, for a constituent that also lacked this relationship to serve as a sufficiently identical antecedent (section 6).24

What we are led to with respect to the constraints on ellipsis is that the identity condition is stated semantically over variable syntactic domains, as per Rooth (1992a). Recall that this was motivated in part by the observation in section 4.3 that TACs are not-at-issue with respect to the QUD and, thus, may not obviously be anteceded by the QUD. Moreover, the identity condition on ellipsis that was adopted made it possible to identify different syntactic constituents as the antecedent for different ellipses. This is how VPE and TAC-Stripping were distinguished in a way that captured their differing distributions. In other words, this makes it possible to understand

possible way to derive a reduced TAC such as (93). If a smaller constituent that did not contain the trace of the temporal operator were elided, the problem of non-parallel binding would not arise. Two possibilities come to mind for why this is not possible: (i) the relevant head that licenses ellipsis of VP, namely $I^0$, is not present as a result of truncation or (ii) the focus movement involved in TAC-Stripping induces a MAXELIDE-type effect that forces ellipsis of the larger vP (e.g., Merchant 2008). Choosing between these options must be left for future research.

It should be pointed out that, in taking this approach, we have lost the ability to account for the ungrammaticality of examples like (i), from Hardt & Romero 2004, which formed part of the empirical domain for Takahashi (2008).

24It should be pointed out that, in taking this approach, we have lost the ability to account for the ungrammaticality of examples like (i), from Hardt & Romero 2004, which formed part of the empirical domain for Takahashi (2008).

(i) Agnes [VP$_1$ arrived after John [VP$_2$ ate $t$]], but Bill didn’t $\Delta_1/\Delta_2$. (Hardt & Romero 2004:384, (34))

It must be left to future research to extend the analysis proposed here in such a way as to help us understand such cases. Alternatively, one might follow the lead of Hardt & Romero (2004) and pursue a discourse-accessibility condition that makes (i) an issue of the recoverability of potential antecedents.
how these two types of ellipsis are differentially eliminative with respect to the phrase structure representations containing TACs.
